## NOTATION

## GLOSSARY

102		
103	Tinikling	The traditional Filipino dance involving two bamboo sticks, where a dancer moves in and out of the rhythmically tapped sticks.
104	OpenCV	An open-source computer vision library widely used for real-time image capture and processing, including camera I/O, preprocessing, filtering, and contour extraction.
105	Ultraleap	A commercial infrared-based hand-tracking system that uses stereo cameras and near-infrared illumination to generate dense, low-latency 3D hand data.
106	MediaPipe	A framework for building multimodal applied machine learning pipelines, including computer vision models like hand gesture recognition.
107	Pose estimation	A computer vision technique used to detect human poses (such as hand or body positions) from images or videos, often used for gesture and movement analysis.
108	Operational Technologies	Programmable systems or devices that interact with the physical environment (or manage devices that interact with the physical environment). These systems/devices detect or cause a direct change through the monitoring and/or control of devices, processes, and events. Examples include industrial control systems, building management systems, fire control systems, and physical access control mechanisms.

111

# INTRODUCTION

## 112      **1.1 Background of the Study**

113      Classical Computer Vision (CV) approaches used skin color segmentation, contour anal-  
114      ysis, optical flow, and handcrafted descriptors (Histogram of Oriented Gradients (HOG),  
115      motion history images) to detect and classify gestures. Despite being simple and inter-  
116      pretable, those methods struggle with background variation and scale. The deep-learning  
117      era replaced handcrafted features with Convolutional Neural Network (CNN)s that learn  
118      hierarchical visual features directly from image data, yielding much higher accuracy for  
119      static hand-pose and short-sequence recognition tasks. Many recent capstone and journal  
120      implementations pair OpenCV (for capture/preprocessing) with CNN built and trained  
121      in TensorFlow/PyTorch to recognize a fixed vocabulary of gestures in real time. These  
122      hybrid pipelines are practical for capstone projects because OpenCV handles efficient frame  
123      processing while CNNs provide generalization across users and backgrounds. Furthermore,  
124      Operational Technologies plays a crucial role in deploying these systems in real-world  
125      applications where physical devices and processes are monitored and controlled, such as  
126      in industrial automation or building management systems, which benefit from enhanced  
127      gesture recognition. (Oudah et al., 2020)

128      Instead of classifying raw images, several high-performance systems first extract skeletal  
129      landmarks (e.g., MediaPipe's 21-point hand model) and feed those coordinates to a classifier  
130      (small CNN, MLP, or temporal model like LSTM). Landmark-based pipelines reduce  
131      sensitivity to background and scale and make models smaller and faster, which is ideal  
132      for mobile or AR deployment. Markerless commercial devices such as the Leap Motion  
133      Controller and Ultraleap cameras provide very accurate 3D joint data using IR illumination  
134      and multi-camera setups; those give superior fidelity but add hardware cost and integration

135 work. For a capstone aiming at broad deployability, a practical approach is to prototype  
136 with MediaPipe + OpenCV + CNN (or lightweight temporal model) and consider Ultraleap  
137 integration later for high-precision installations. (Zhang et al., 2020)

## 138 **1.2 Prior Studies**

139 Prior research on the topic at hand has shown substantial progress in the integration of pose  
140 estimation, computer vision, and interactive technologies for the sake of movement-based  
141 learning. For instance, a study by Kim et al. (2023) presents a human pose estimation  
142 method which integrates MediaPipe Pose with additional optimization techniques in order  
143 to improve its accuracy and robustness. The designed framework is capable of real-time  
144 landmark detection through the use of only a single RGB camera, while optimization meth-  
145 ods such as smoothing filters and Kalman filtering are used to reduce jitter and improve the  
146 temporal consistency. Results depicted a high detection accuracy for various body parts,  
147 with its performance remaining stable under varying lighting and background. This shows  
148 MediaPipe's suitability for real-time applications where both speed and stability is crucial,  
149 especially in aspects such as gesture recognition, sports monitoring, and motion analysis.  
150 Tharatipyakul et al. (2024) explores various deep learning-based human pose estimation  
151 techniques and their applications in health, rehabilitation, and human motion analysis. The  
152 paper looks into both 2D and 3D pose estimation. It is noted that 2D methods are widely  
153 used for real-time applications as they have much lower computational requirements in  
154 comparison to 3D. Deep convolutional neural networks and transformer-based models  
155 proved to significantly improve the landmark localization accuracy in comparison to classi-  
156 cal approaches. Ultimately, the paper emphasized that integrating temporal information

157 enhances performance in sequential movement tasks, making these methods highly relevant  
158 for motion learning, sports training, and interactive systems. El Raheb et al. (2019) focuses  
159 on interactive dance learning systems and how such technology has the potential to support  
160 dance pedagogy through utilizing real-time feedback and structured interaction workflows.  
161 Multiple systems were analyzed and, afterwards, a framework was perfected which made  
162 use of motion capture, real-time analysis, and visual feedback in order to support users,  
163 who are both learners and instructors. Key interaction patterns were identified such as  
164 mirroring, guidance, and correction, which enhances the overall learning experience and, in  
165 turn, effectiveness. It also looks into usability considerations such as responsiveness, clarity  
166 of feedback, and alignment with existing teaching approaches, which is relevant to the  
167 creation of dance learning systems. Ultimately, such studies depict the intersection of pose  
168 estimation, feedback systems, and immersive interfaces, which lays a strong groundwork  
169 for future developments in digital dance education and interactive movement learning  
170 systems.

### 171 1.3 Problem Statement

172 To this day, the national dance of the Philippines known as ‘Tinikling’ continues to hold  
173 cultural significance among students, educators, and dance enthusiasts. However, despite its  
174 importance, those that aspire to learn the dance lack access to physical classes or qualified  
175 instructors be it due to geographical or time constraints. Existing methods of learning  
176 may be costly or unable to provide feedback to the student in real-time, which makes the  
177 learning process difficult for individuals in terms of practicing effectively on their own.  
178 Such a gap highlights the need for a much more accessible, interactive, and accurate tool

179 which would be able to guide learners remotely in an efficient manner and, ultimately,  
180 ensuring that tradition is preserved and passed on to future generations.

181 **1. PS1:**

182 • The ideal scenario for our intended audience (students, educators, and dance  
183 enthusiasts) is to have an intuitive and interactive learning tool that facilitates  
184 the practice of Tinikling, the traditional Filipino dance. This tool should provide  
185 real-time feedback on users' dance movements, enabling them to learn and  
186 improve their technique. The desired state includes accessibility to the tool on  
187 various devices (e.g., desktop, mobile) with a user-friendly interface and a high  
188 level of accuracy in tracking the dance steps. Additionally, it should support  
189 personalized feedback, enabling users of all skill levels to progress and feel  
190 engaged in learning this cultural heritage.

191 **2. PS2:**

192 • Currently, learning Tinikling requires access to physical dance classes or in-  
193structors, which are often limited by geographical location, financial resources,  
194 or time constraints. For individuals unable to attend such classes, the lack of af-  
195 fordable and effective learning tools becomes a significant barrier. Additionally,  
196 existing dance-learning technologies are either costly, relying on specialized  
197 hardware, or lack the immediacy of real-time feedback, making it difficult  
198 for learners to practice and perfect their movements without direct instructor  
199 guidance.

- 200 • The pain point is that students who want to practice Tinikling at home or in  
201 remote areas are unable to receive real-time guidance or feedback, leading to  
202 slower progress, incorrect technique, and a loss of motivation.

203 **3. PS3:**

- 204 • Without a tool that offers immediate feedback and a clear learning path, students  
205 practicing Tinikling on their own are likely to struggle with incorrect move-  
206 ments, which may lead to frustration. Over time, this lack of progress could  
207 result in a lack of confidence, disengagement from the learning process, and  
208 ultimately, the inability to learn the dance correctly. Furthermore, the absence  
209 of accessible learning tools risks the loss of cultural knowledge and the fading  
210 of the Tinikling tradition, especially among younger generations who may not  
211 have easy access to traditional learning methods.

212 **1.4 Objectives and Deliverables**

213 **1.4.1 General Objective (GO)**

- 214 • GO: To design and implement a real-time Pose estimation-based Tinikling learning  
215 application;

216 **1.4.2 Specific Objectives (SOs)**

- 217 • SO1: To develop a real-time pose estimation pipeline that captures dancers' move-  
218 ments using a webcam, detects key skeletal landmarks, and analyzes Tinikling steps

219 with at least 30 frames per second (fps) processing speed and  $\geq$  90% detection  
220 accuracy.;;

- 221 • SO2: To make the pose estimation model robust to lighting, background clutter,  
222 and user variation through dataset collection and augmentation and, landmark-based  
223 representations while maintaining a minimum pose detection accuracy of 85% ;
- 224 • SO3: To design and integrate a scoring and feedback system that evaluates user perfor-  
225 mance by aligning poses with reference choreographies, providing numerical scores  
226 (0–100) and step-by-step accuracy breakdown within 1 second after performance.;
- 227 • SO4: To evaluate the system’s performance and usability through controlled test-  
228 ing with at least 10 participants, measuring pose estimation accuracy, latency, and  
229 user satisfaction ( $\geq$  80% positive feedback) using standardized questionnaires and  
230 performance metrics.;

231 **1.4.3 Expected Deliverables**

TABLE 1.1 EXPECTED DELIVERABLES PER OBJECTIVE

Objectives	Expected Deliverables
GO: To design and implement a real-time Pose estimation-based Tinikling learning application	<ul style="list-style-type: none"> <li>• Prototype of Tinikling learning application.</li> <li>• Documentation and user manual.</li> </ul>
SO1: To develop a real-time pose estimation pipeline that captures dancers' movements using a webcam, detects key skeletal landmarks, and analyzes Tinikling steps with at least 30 frames per second (fps) processing speed and $\geq 90\%$ detection accuracy.	<ul style="list-style-type: none"> <li>• Optimized skeletal keypoints detection for Tinikling steps.</li> <li>• Implementation of webcam-based pose estimation pipeline.</li> <li>• Performance evaluation results.</li> </ul>
SO2: To make the pose estimation model robust to lighting, background clutter, and user variation through dataset collection and augmentation and, landmark-based representations while maintaining a minimum pose detection accuracy of 85%	<ul style="list-style-type: none"> <li>• Augmented dataset covering varied lighting, backgrounds, and user types.</li> <li>• Enhanced landmark-based model with robustness improvements.</li> <li>• Comparative performance evaluation report.</li> </ul>
SO3: To design and integrate a scoring and feedback system that evaluates user performance by aligning poses with reference choreographies, providing numerical scores (0–100) and step-by-step accuracy breakdown within 1 second after performance.	<ul style="list-style-type: none"> <li>• Scoring and feedback algorithm.</li> <li>• Tinikling choreography database.</li> <li>• Post-performance scoring output with accuracy metrics.</li> </ul>
SO4: To evaluate the system's performance and usability through controlled testing with at least 10 participants, measuring pose estimation accuracy, latency, and user satisfaction ( $\geq 80\%$ positive feedback) using standardized questionnaires and performance metrics.	<ul style="list-style-type: none"> <li>• Conducted controlled testing with participants.</li> <li>• Collected performance and usability metrics.</li> <li>• Evaluation report with recommendations for improvement.</li> </ul>

## 232      **1.5 Significance of the Study**

233      This capstone project focuses on the development of a Tinikling learning application  
234      through the integration of pose estimation and human action recognition. The setup consists  
235      of a webcam, laptop, and two bamboo sticks for the Tinikling dance. Such a setup offers  
236      affordability and accessibility benefits for users. Ultimately, it contributes to the field  
237      of both pose estimation and human action recognition by demonstrating a successful  
238      integration of the two in a live setup.

### 239      **1.5.1 Technical Benefit**

- 240      1. Enables real-time pose estimation and post-performance feedback, improving accu-  
241      racy and efficiency throughout the learning process.
- 242      2. Low-cost software-based learning tool which uses a webcam and desktop computer  
243      rather than expensive motion capture equipment.

### 244      **1.5.2 Social Impact**

- 245      • Promotes cultural preservation by making Tinikling more accessible through interac-  
246      tive applications.
- 247      • Increases student engagement and participation via gamified learning.
- 248      • Supports remote or in-classroom instruction by enabling technology-assisted dance  
249      education.

250 **1.5.3 Environmental Welfare**

- 251 • Utilizes existing and widely available hardware such as webcams and desktop computers rather than new specialized equipment, which ultimately lessens electronic  
252 waste.  
253  
254 • Encourages digital preservation of cultural heritage, lessening reliance on physical  
255 materials or infrastructure.

256 **1.6 Assumptions, Scope, and Delimitations**

257 **1.6.1 Assumptions**

- 258 1. Pose landmarks from webcams with standard RGB resolutions such as 720p, 1080p,  
259 and 4K or low-cost depth sensors provide sufficient fidelity to represent Tinikling  
260 movements for temporal alignment and scoring.  
261  
262 2. Choreography can be divided into short, labeled segments that enable reliable match-  
263 ing and targeted feedback.  
264  
265 3. Dynamic Time Warping or a constrained variant will handle tempo variation robustly  
266 for temporal alignment.  
267  
268 4. A brief per-user calibration step will improve scoring consistency.

266 **1.6.2 Scope**

- 267 1. Cover automatic pose estimation, sequence alignment, and segment-level scoring for  
268 Tinikling.

- 269        2. Accept landmark or depth inputs and provide immediate on-device cues during  
270              performance.
- 271        3. Produce a higher-precision final score after a more detailed pass.
- 272        4. Use self-sourced Tinikling videos for model training when no public dataset exists.
- 273        5. Benchmark against general dance datasets where appropriate.
- 274        6. Report sensor-based metrics and simple user measures such as perceived accuracy  
275              and engagement.

276        **1.6.3 Delimitations**

- 277        1. Will not perform detailed facial or hand mesh reconstruction.
- 278        2. Will not replace multi-camera motion capture for research-grade kinematics.
- 279        3. Will not guarantee reliable results under heavy occlusion, very low light, extreme  
280              off-axis views, or when clothing blends with the background.
- 281        4. Will not attempt full generalization to all body shapes without additional data and  
282              tuning.
- 283        5. Limits reflect known sensor and algorithm constraints and the aim to produce a  
284              practical, lightweight prototype.

## 1.7 Description and Methodology of the Capstone Project on Operational Technologies

1. Phase 1: Model Development serves as a precursor for Phase 2 wherein the specifics of the model, libraries, and environment to use are defined. In total, Phase 1 would last 4 weeks spanning from week 4 to 7. The bulk of the research for the project would be carried out during this phase. The dataset to be used for training would be collected during this phase as well.
2. Phase 2: Model Training consists of training the model using the dataset collected in the previous phase. This phase will largely consist of testing and improving the resulting model. Tests would be conducted using the group members as dancers. This phase also includes the optimization of the model for real-time detection simultaneously with the music. In total, this phase would last 4 weeks spanning from week 8 to 11.
3. Phase 3: UI/UX Development consists of the integration of the trained model with a user interface. Once integrated final testing and refinement of the final program would be carried out. The final output would be presented as well during this phase along with the finalization of the documentation. This phase would last for 3 weeks spanning from week 11 to 13.

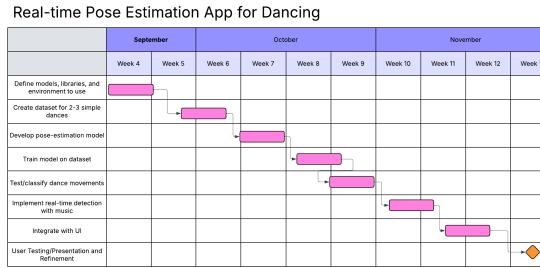

Fig. 1.1 Milestone Gantt Chart for Real-time Pose Estimation Dance Software

303

## 1.8 Estimated Work Schedule and Budget

304

### 1.8.1 Milestones and Gantt Chart

305

### 1.8.2 Budget

306

Given that the capstone project largely consists of software, apart from the use of a laptop for both programming, as well as actual implementation and usage of the dance program, the only expense to consider would be for that of a Webcam, which is already owned.

307

308

TABLE 1.2 OPERATIONAL FINANCIAL PLAN

Item	Price
Webcam	P1,850
4pc. Tinikling Sticks	P110
<b>Total</b>	<b>P1,960</b>

## 309    **1.9 Overview of the Capstone Project on Operational 310    Technologies**

311    This capstone project focuses on developing a real-time pose estimation-based learning  
312    application for Tinikling, the Philippine national dance. It integrates computer vision  
313    and machine learning techniques in order to create an interactive learning platform that  
314    provides performance scoring to users. The project utilizes webcams and MediaPipe-based  
315    skeletal landmark extraction to analyze users' movements relative to reference choreography.  
316    Unlike expensive motion capture systems, this setup uses low-cost and accessible hardware,  
317    making the system practical for classroom, cultural, and home use. The system emphasizes  
318    cultural preservation by modernizing Tinikling education through technology. It enables  
319    students to learn and practice the dance interactively, provides technical benefits such as  
320    real-time feedback without costly sensors, and supports social and environmental goals  
321    through cultural engagement and sustainable use of existing hardware.

De La Salle University

322

## Chapter 2

323

## LITERATURE REVIEW

## 324 2.1 Existing Work

325 A study by Venkatrayappa et al. (2024) focused on surveying the various existing 3D  
326 human body pose and shape estimation techniques, given its crucial nature in fields such  
327 as augmented or virtual reality, healthcare and fitness technology, and virtual retail. The  
328 solutions explored consisted of mainly three types of inputs, which were single images,  
329 multi-view images, and videos. Various issues pertaining to dance, such as fast motion,  
330 occlusion, and unusual poses were analyzed to see how each affected the performance  
331 of each method. The specific models consisted of SMPL -A, SMPL -X, MANO, STAR,  
332 FLAME, which are optimization-based models, as well as HMR, VIBE, SPIN, PARE,  
333 EXPOSE, and PHALP, which are deep learning-based models. SMPL was found to be  
334 beneficial in terms of realistic body representation, efficiency for real time applications, and  
335 wide availability, however it has limitations in areas pertaining to facial and hand modeling,  
336 as well as representation of ethnic diversity. SMPL -X proved to provide several advantages  
337 such as facial expressions, hand gestures, and improved expressiveness. Its limitations,  
338 however, consisted of simplified hand modeling and its limited pose variability. MANO  
339 offers detailed hand gesture modeling and realistic hand deformations, but has limitations  
340 due to its focus being exclusively on the modeling of hands, as well as computational  
341 challenges. STAR leverages sparse coding and temporal modeling, which allowed for  
342 a much more powerful framework for pose estimation., depicting state-of-the-art results  
343 throughout various benchmarks and practical implementations in sports analysis, human-  
344 computer interaction, and VR. FLAME was advantageous when it comes to computational  
345 efficiency, which made it suitable for real-time applications of pose estimation. As for its  
346 limitations, it primarily focuses on facial and lip modeling, which introduces complexity

# De La Salle University

347 and potential computational challenges. MANO, HMR produces richer and more useful  
348 mesh representation, which is parameterized by shape and 3D joint angles. The network  
349 implicitly learns the angle limits of each joint. As such its use is discouraged for people  
350 with unusual body shapes. Its re-projection loss is highly under-constrained and it needs  
351 adversarial supervision in order to avoid unrealistic outputs. VIBE makes use of CNNs,  
352 RNNs and GANs, as well as a self-attention layer in order to achieve state-of-the-art  
353 results. A motion discriminator is used to help produce more realistic motion. Ultimately,  
354 the model is a standard SMPL body model format with sequences of poses and shape  
355 parameters. SPIN makes use of a self improving loop wherein better fits allow the network  
356 to train in a much more efficient manner while better initial estimates from the network  
357 aids the optimization routine in order to result in better fits. PARE consists of a guided  
358 attention mechanism which exploits information on visibility of individual body parts all  
359 the while leveraging information from neighboring body parts in order to predict parts  
360 which are occluded. EXPOSE includes body, face, and hand estimation. It is able to  
361 estimate expressive 3D humans in a much more accurate manner in comparison to existing  
362 optimization methods at only a fraction of the computational costs. PHALP out performs  
363 all of the aforementioned methods. Despite this, it still has its limitations as well such as its  
364 reliance on a single camera, which may lead to issues such as occlusion and motion blur. It  
365 may also not work well in low-light conditions or when a person's clothes is a similar color  
366 to that of the background. Lastly, it also requires a significant amount of computational  
367 resources, which may make it not suitable for real-time applications.

368 A study by Protopapadakis et al. (2018), analyzes the effectiveness of various classifica-  
369 tion techniques in recognizing different dance types based on motion-capture skeleton data.  
370 Classifiers explored consisted of k-Nearest Neighbors (k-NN), Naïve Bayes, Discriminant

# De La Salle University

371 Analysis, Classification Trees, Random Forests (TreeBagger), Support Vector Machines  
372 (SVMs), and Ensemble Classifiers. Poses are identified through the use of body joints via  
373 Kinect sensor. The data set used consisted of various dances such as Enteka, Kalamatianos,  
374 Syrtos (Two-beat), Sytros (Three-beat). The kinect was used to capture skeletal joining  
375 data, to which feature extraction techniques such as principal component analysis and frame  
376 differencing were used in order to improve the classification accuracy. Ultimately, results  
377 showed that k-nearest neighbors and random forests are the best-performing classifiers  
378 among those that were explored. It was also proposed that the use of mulit-sensor or  
379 multimodal data may serve as a potential solution for issues specific to pose recognition in  
380 dance such as occlusion and complex movement patterns.

381 A study by Zhao et al. (2025), looks into dance pose estimation and introduces the model  
382 DanceFormer. DanceFormer is a transformer-based model for dance pose estimation which  
383 makes use of the Vision Transformer, Time Series Transformer, and an edge computation  
384 layer in order to achieve a deep fusion of multimodal features and to overall increase  
385 its accuracy and real-time performance. The AIST and DanceTrack datasets were used  
386 throughout the experimentation. Results showed that DanceFormer out performs other  
387 models, with it achieving a pose estimation accuracy or MPJPE of 18.4mm and 20.1mm,  
388 as well as a multi-object tracking accuracy or MOTA of 92.3% and 89.5%. It is also  
389 suitable for real-time processing in even low-resource with an average latency of 35.2ms.  
390 Ultimately, it serves as an efficient, precise and real time solution for rather complex dance  
391 scenarios. It also has applications in a much more broad sense be it in dance education or  
392 in real-time motion analysis.

393 A study by Lei et al. (2023) discusses dance movement recognition based on gesture. A  
394 low accuracy traditional dance movement recognition algorithm based on human posture

# De La Salle University

395 estimation was proposed. PAFs algorithm was used in order to recognize the spatial skeleton  
396 nodes and connections of joints in the human body. The pose of the body is estimated based  
397 on the movement of the spatial skeleton. Once the information on the detected posture  
398 is preprocessed and its features are extracted, LTSM time series algorithm was used in  
399 order to classify and recognize certain dance movements. Ultimately, results showed that  
400 the proposed algorithm has the capacity to reliably identify dance movements based on  
401 the skeleton nodes. It was able to achieve a recognition accuracy and recall rate upwards  
402 of 85% for the different movement categories. As for its recognition accuracy of curtsey  
403 movement, it achieved upwards of 95.2%.

404 Tölgessy et al. (2021) present a detailed evaluation of Kinect v1, Kinect v2, and Azure  
405 Kinect skeleton tracking, analyzing joint-level error distributions and repeatability across  
406 distances and orientations. Their results highlight degradation in accuracy under occlusion,  
407 off-axis angles, and larger working distances, conditions typical of casual living-room dance  
408 setups. The findings underline both the potential and the limits of Kinect-class sensors,  
409 suggesting that practical applications often require either sensor fusion and smoothing to  
410 handle jitter or a focus on more reliable joints for robust real-time scoring.

411 Lin (2015) investigate how interactive feedback design influences user motivation in  
412 the context of Just Dance. Their study demonstrates that timely, clear cues significantly  
413 improve engagement, perceived competence, and sustained participation, with direct effects  
414 on physical activity outcomes. These findings show that feedback modalities and latency  
415 are as critical as recognition accuracy in shaping the player experience, emphasizing  
416 the importance of immediate, multimodal responses in dance or pose-based teaching  
417 applications.

418 Yu and Xiong (2019) propose and validate a Dynamic Time Warping method for

# De La Salle University

419 evaluating rehabilitation exercises tracked with Kinect. Their algorithm successfully aligns  
420 noisy, tempo-varying motion with reference trajectories, producing reliable correctness  
421 scores even with partial occlusion. Applied to dance or short choreographies, DTW offers  
422 a robust foundation for handling tempo shifts and timing variation, supporting sequence-  
423 based scoring that is more forgiving than strict frame-to-frame comparison.

424 Rallis et al. (2019) compare Kinect II with the high-precision Vicon system in the  
425 context of choreography retrieval and analysis, using trajectory similarity measures such  
426 as DTW. While Kinect data contain noise and smoothing artifacts, the study shows that  
427 trajectory-level patterns remain useful when algorithms are designed to tolerate sensor  
428 bias. Their results support the use of low-cost consumer sensors, including RGB landmark  
429 pipelines, in applications where robust temporal alignment and trajectory modeling can  
430 offset hardware limitations.

431 Human pose estimation (HPE) has become an important area of study due to its applica-  
432 tions in action recognition, sports, and performing arts. Xu, Zou, and Lin (2022) introduced  
433 the Adaptive Hypergraph Neural Network (AD-HNN), which captures high-order semantic  
434 dependencies among joints to improve multi-person pose estimation, particularly in han-  
435 dling occlusion and pose variability. In dance analysis, Ju (2025) applied deep learning with  
436 ResNet-152 and HR-Net to enhance dance pose recognition, addressing class imbalance  
437 and improving classification accuracy through global-local feature fusion.

438 For cultural preservation, motion capture (MoCap) has been widely adopted. Rizhan  
439 et al. (2025) demonstrated the use of MoCap to develop authentic motion templates for  
440 Malay folk dances, ensuring accuracy and authenticity in preserving intangible cultural  
441 heritage. In addition, Büyükgökoğlan and Uğuz (2025) developed a performance evaluation  
442 system for Turkish folk dances using deep learning-based pose estimation (e.g., Mediapipe,

443 YOLO, LSTM), enabling objective assessment compared to traditional jury scoring.

TABLE 2.1 SUMMARY OF REVIEWED DANCE POSE ESTIMATION AND RECOGNITION STUDIES

Paper	Focus	Methodology	Results
<i>Venkatrayappa et al. (2024)</i>	Evaluates 3D human pose & shape estimation techniques for dance	PHALP (multi-frame 3D pose estimation)	N/A
<i>Protopapadakis et al. (2018)</i>	Identifies dance types using skeletal data	k-NN classifier on PCA-reduced Kinect skeleton features	Accuracy = 0.52
<i>Zhao et al. (2025)</i>	Seeks accurate, real-time pose estimation for complex dances	Hybrid Vision + Time-Series Transformer (DanceFormer)	MPJPE = 18.4/20.1 mm; MOTA = 92.3% / 89.5%; Latency = 35.2 ms
<i>Lei et al. (2023)</i>	Improves low-accuracy traditional-dance recognition methods	PAF-based keypoint detection + LSTM classifier	>85% overall; 95.2% (curtsey)
<i>Ju (2025)</i>	Proposes deep-learning methods to design & recognize dance poses	ResNet-152 + HRNet (global-local feature fusion)	Accuracy = 0.9870; Precision = 0.9851; Kappa = 0.9841
<i>Xu et al. (2022)</i>	Estimates multiple human poses from single images using an adaptive structure	Adaptive Hypergraph Neural Network (AD-HNN)	AP = 76.6% (COCO)
<i>Tölgessy et al. (2021)</i>	Evaluates joint-level accuracy and repeatability across Kinect sensors	Kinect V1 / V2 / Azure skeleton-tracking evaluation	Std. Dev. = 0.8–1.9 mm; Joint misses = 15–30%
<i>Yu &amp; Xiong (2019)</i>	DTW-based scoring for Kinect-based rehabilitation/exercise	DTW-based scoring of Kinect-derived skeleton motions	Pearson $r$ = 0.86
<i>Rallis et al. (2019)</i>	Choreography pattern analysis (Kinect vs Vicon)	DTW trajectory matching (Kinect II vs Vicon)	N/A
<i>Sun &amp; Song (2025)</i>	Pose estimation in complex dance scenes	Improved HRNet + CBAM attention + multi-scale fusion	Accuracy = 73.5% (MPII); 79.5% (dance dataset)
<i>Bityükgökoglan &amp; Uğuz (2025)</i>	Deep-learning-based scoring for Turkish folk dance	MediaPipe / YOLO pose extraction + LSTM scoring	LSTM = 68.43 (MSE = 56.11); DTW = 60.64 (MSE = 139.32)

## 444 2.2 Lacking in the Approaches

445 These studies show the potential of pose estimation and deep learning for advancing  
 446 both modern dance movement design and traditional folk dance preservation. How-

447 ever, there is little to no research in the Philippines that applies pose estimation to folk  
448 dances—particularly Tinikling—representing a significant gap and opportunity for future  
449 exploration.

450 **2.3 Summary**

451 Research on human pose estimation (HPE) spans multiple applications including AR/VR,  
452 healthcare, and dance. Optimization- and deep learning-based models (e.g., SMPL, SMPL-  
453 X, HMR, VIBE, SPIN, PARE, EXPOSE, PHALP) have been studied for realistic 3D  
454 body reconstruction (Venkatrayappa et al., 2024). Dance classification has been explored  
455 using skeleton data and machine learning classifiers like k-NN and Random Forest (Pro-  
456 topopadakis et al., 2018). Transformer-based models such as DanceFormer achieve high  
457 accuracy and real-time performance in dance pose estimation (Zhao et al., 2025), while  
458 PAF- and LSTM-based algorithms improve movement recognition (Lei et al., 2023). Kinect  
459 studies reveal both potential and limits in low-cost motion capture (Tölgessy et al., 2021;  
460 Rallis et al., 2019), while feedback and sequence-alignment approaches (Lin et al., 2015;  
461 Yu & Xiong, 2019) highlight the importance of interactivity and temporal robustness.

462 Recent work integrates advanced neural networks for pose estimation, such as adaptive  
463 hypergraphs (Xu et al., 2022), deep feature fusion for dance poses (Ju, 2025), MoCap  
464 for authentic folk dance templates (Rizhan et al., 2025), and deep learning systems for  
465 evaluating Turkish folk dance (Büyükgökoğlan & Uğuz, 2025).

466

## Chapter 3

467

# THEORETICAL CONSIDERATIONS

### 468      **3.1 Human Pose Estimation**

469      Human pose estimation is the process of predicting the pose of human body parts. The data  
470      are typically derived from RGB images or videos. Given that certain motions are motivated  
471      by human actions, detecting poses is a critical aspect of human action recognition (Song  
472      et al., 2021). It has a wide range of applications such as human-computer interaction,  
473      motion analysis, augmented reality, and virtual reality. The resulting output of human pose  
474      estimation is a skeleton-like representation of the human body consisting of nodes and  
475      limbs (Zheng et al., 2020). There are two main types of human pose estimation, namely 2D  
476      and 3D. 2D pose estimation consists of predicting the posture of each of the body's key  
477      points in a 2D plane, considering the X and Y axes. As for 3D pose estimation, it considers  
478      the Z axis, situating each point in a 3D space. It goes without saying that 3D estimation is  
479      more difficult in comparison to 2D estimation in process and complexity due to underlying  
480      issues such as noisy backgrounds, clothing, lighting, undetected joints, or occlusion (Ben  
481      Gamra & Akhloufi, 2021).

### 482      **3.2 Human Action Recognition**

483      Human action recognition (HAR) is the process of detecting human actions to classify  
484      them through single-sensor data, RGB image or video data, or three-dimensional depth  
485      and inertial data (Sakar et al., 2022). In the field of computer vision, one of the most  
486      challenging aspects is the automatic and precise identification of human activity. Over the  
487      years, there has been a significant increase in feature learning-based representations for  
488      human action recognition as a result of the widespread utilization of deep learning-based  
489      features. There are various applications of HAR — for instance, automated surveillance

# De La Salle University

systems that make use of AI and machine learning algorithms to identify human actions for safety and security. Such tasks, however, are made difficult due to factors such as changing environments, occlusion, different viewpoints, execution pace, and biometric variation. Furthermore, the human body varies from person to person in factors such as size, appearance, and shape. However, advancements in Convolutional Neural Networks (CNNs) have resulted in significant progress in human action recognition through improvements in classification, segmentation, and object detection. This largely applies to image-related tasks rather than videos, as neural network models struggle to capture temporal information in videos due to the lack of substantial datasets (Morshed et al., 2022).

De La Salle University

499

## Chapter 4

500

# DESIGN CONSIDERATIONS

## 501 4.1 Sensor Choice, Representation, and Robustness

502 A study by Tölgessy, Dekan, and Chovanec (2021) demonstrated that Kinect-family depth  
503 sensors produce explicit 3D skeletons and give higher joint fidelity in controlled settings,  
504 but the accuracy falls with occlusion, off-axis views, and increased distance. Zhang et  
505 al. (2020) described MediaPipe, which yields compact 2D/3D landmark coordinates from  
506 ordinary RGB cameras and runs in real time on mobile devices. Therefore, designers often  
507 choose landmarks for rapid, lightweight prototypes and mobile deployment, and reserve  
508 depth or IR systems for installation-grade fidelity when hardware is available. To reduce  
509 real-world failure modes, practitioners apply photometric and background augmentation  
510 and synthetic occlusions during training, and they add a short calibration step so system  
511 metrics align with an individual user's range of motion.

## 512 4.2 Temporal Alignment and Scoring

513 Dance is a temporal activity and should be compared as a sequence rather than as isolated  
514 frames. Yu and Xiong (2019) demonstrate that Dynamic Time Warping (DTW) can align  
515 noisy, tempo-varying Kinect skeleton sequences and convert DTW distances into mean-  
516 ingful performance scores. Rallis et al. (2019) apply DTW to choreographic trajectories  
517 and show it can match patterns across high-precision (VICON) and low-cost (Kinect)  
518 capture systems. Thus, a practical scoring pipeline first aligns sequences with DTW (or a  
519 constrained variant) and then evaluates local spatial metrics such as joint-angle differences  
520 or normalized trajectory distances to produce interpretable, per-segment correctness scores.

### 521     **4.3 Real-Time Feedback, Segmentation, and Peda-** 522         **gogy**

523     Lin (2015) finds that immediate, clear feedback in dance exergames improves engagement  
524     and supports learning. Zhang et al. (2020) show that on-device landmark extraction can  
525     run at real-time rates suitable for low-latency feedback. Combining these results suggests  
526     a two-tier runtime design: use a fast, coarse matcher (enabled by on-device landmarks)  
527     for instant cues, and run a slower, higher-precision alignment and scoring pass for final  
528     grading. Breaking choreography into short labeled segments also simplifies alignment and  
529     reduces error accumulation; Rallis et al. (2019) illustrate that segment- or trajectory-level  
530     matching better supports choreographic retrieval and per-segment feedback.

### 531     **4.4 Accessibility, Personalization, and Evaluation**

532     Yu and Xiong (2019) convert DTW distances into calibrated percentage scores, which  
533     supports per-user calibration and comparison against an individualized baseline. Tölgessy  
534     et al. (2021) recommend measuring sensor-level metrics such as joint error and dropout rates  
535     when choosing a capture modality. Therefore, system designs should include adjustable  
536     sensitivity, alternate gesture mappings, and user profiles, and evaluation should combine  
537     sensor metrics (joint error, dropout, latency) with human-centered measures (perceived  
538     accuracy, engagement, and learning gain) to justify architecture and scoring choices.

539

# METHODOLOGY

541

## 5.1 Methodology

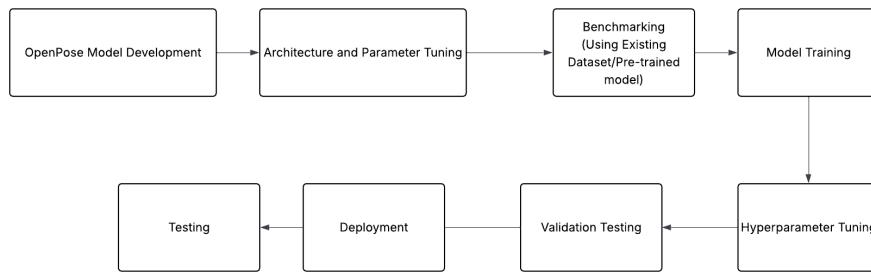

Fig. 5.1 Methodology Block Diagram

542

### 5.1.1 Methodology Overview

543

This project develops a desktop real-time pose-estimation application for Tinikling learning.

544

The pipeline comprises (1) dataset collection and annotation, (2) real-time landmark detection using MediaPipe with OpenCV preprocessing, (3) model robustness improvements

545

via augmentation and fine-tuning, (4) a per-segment scoring and feedback engine, and (5)

546

system evaluation and user studies for performance and usability.

547

548

## 5.1.2 Dataset Collection and Annotation

549

We collect Tinikling performances using consumer webcams across varied environments (lighting, backgrounds, participant clothing). Each recording is annotated with segment boundaries and ground-truth reference trajectories for the core Tinikling steps. Annotation files follow a simple CSV schema: frame index, timestamp, keypoint coordinates (x,y[,z if available]), and segment label.

550

551

552

553

### 554 5.1.3 Real-time Pipeline (Implementation)

555 The real-time pipeline components:

556 1. **Capture & Preprocessing:** Acquire frames from webcam at target frame rates; apply  
557 resizing, color normalization, and optional background subtraction using OpenCV.

558 2. **Landmark Detection:** Run MediaPipe Pose to extract 2D/3D keypoints; post-  
559 process landmarks (smoothing, confidence thresholding).

560 3. **Segmentation & Alignment:** Detect segment boundaries (simple heuristics or  
561 learned segment classifier), then align performed segment to reference via DTW or  
562 constrained alignment.

563 4. **Scoring & Feedback:** Compute per-joint and per-segment metrics; convert distances  
564 to 0–100 scores, present instant cues (visual/audio) and detailed breakdowns in UI.

565 5. **Logging & Persistence:** Save session logs, computed metrics, and anonymized  
566 recordings for later analysis.

### 567 5.1.4 Model Robustness and Training

568 To improve robustness:

- 569 • Augment datasets with photometric (brightness/contrast), geometric (rotation, scale),  
570 and synthetic occlusion transforms.
- 571 • Perform k-fold validation and ablation studies to measure the effect of augmentations.

- 572 • Where appropriate, fine-tune a lightweight backbone (e.g., MediaPipe-compatible net-  
 573 work) or add a small temporal refinement network (multi-frame fusion) for increased  
 574 temporal stability.

### 575 5.1.5 Scoring, Calibration, and UX

576 Scoring converts aligned distances into interpretable percentages per segment:

$$\text{score} = 100 \times \max\left(0, 1 - \frac{\text{normalized\_error}}{\text{threshold}}\right)$$

577 Calibration includes per-user baseline capture (neutral stance and sample steps) to normalize  
 578 per-joint tolerances. UI design emphasizes low-latency cues for learning (immediate  
 579 feedback) and a post-run breakdown for correction.

### 580 5.1.6 Evaluation Plan

- 581 1. **Automated metrics:** Detection accuracy (%), MPJPE where available, processing  
 582 fps, latency (ms).
- 583 2. **User study:**  $n \geq 10$  participants performing a standardized Tinikling routine;  
 584 questionnaires to measure perceived accuracy, ease-of-use, and satisfaction. Target:  
 585  $\geq 80\%$  positive feedback.
- 586 3. **Robustness tests:** Evaluate under varied lighting, occlusion, and viewpoint condi-  
 587 tions; measure drop in accuracy and suggest mitigations.
- 588 4. **Report:** Compile results, run statistical tests where applicable, and provide actionable  
 589 recommendations.

590 **5.1.7 Deliverables**

- 591 • Desktop application with installer and README (architecture, usage, install).
- 592 • Annotated dataset subset and reference choreography library.
- 593 • Evaluation report including metrics, user-study results, and recommendations.
- 594 • Source code release and simple reproducibility instructions.

595 **5.2 Summary**

596 This methodology outlines a practical pipeline to build and evaluate a real-time Tinikling  
597 learning tool: dataset creation, MediaPipe-based real-time detection with OpenCV optimi-  
598 zations, augmentation and fine-tuning for robustness, DTW-based alignment and scoring,  
599 and human-subject evaluation for usability and performance validation.

601

# RESULTS AND DISCUSSIONS

602 Show in this chapter proofs why your proposed solution works. However, presenting  
 603 results ("It worked") without an appropriate explanation does not show thorough under-  
 604 standing. Aside from the data and results that you have obtained, and their explanation, the  
 605 discussion includes why components of your proposed solution worked or did not work in  
 606 accordance to what you described in the evaluation process, and how the proposed solution  
 607 performed and fared. Interpret the results and the reasons why they were obtained. If  
 608 your results are incorrect, apparent discrepancies from theory should be pointed out and  
 609 explained. In essence, what do the results mean? Citing existing publication can help you  
 610 compare your results and your explanations.

611 The next items below are not related to the description of this results and discussions  
 612 chapter, but serve as an opener for the L<sup>A</sup>T<sub>E</sub>X portion of this template.

613 Here is an example of a citation for ISO 80000-2 standard ?. Another one is ? and ?.

614 In using this template, the user is expected to have a working knowledge of L<sup>A</sup>T<sub>E</sub>X. A  
 615 good introduction is in ?. Its latest version can be accessed at <http://www.ctan.org/tex-archive/info/lshort>. See the Appendix of document\_guide.pdf for examples.

616  
 617 In aggregate form, Table 6.1 shows the outcomes and completions in applying the  
 618 methodology of the Capstone Project on Operational Technologies per objective.
